1Exam template credit: http://www-math.mit.edu/~psh
1. Let

\[ f(x) = \begin{cases} 
1 & \text{when } 0 \leq x \leq L, \\
0 & \text{when } -L \leq x < 0.
\end{cases} \]

(a) (5 points) Find the Fourier series \( \mathcal{F}(x) \) of \( f(x) \) on \([-L, L]\)

Solution: Notice that the function is neither even nor odd. Hence we have to find all the terms. We start with \( a_0 \)

\[ a_0 = \frac{1}{L} \int_{-L}^{L} f(x) \, dx = \frac{1}{L} \int_{0}^{L} 1 \, dx = 1. \]

Then \( a_n, n = 1, 2, \ldots \),

\[ a_n = \frac{1}{L} \int_{-L}^{L} f(x) \cos\left(\frac{n\pi x}{L}\right) \, dx = \frac{1}{L} \int_{0}^{L} 1 \cos\left(\frac{n\pi x}{L}\right) \, dx \]

\[ = \frac{1}{L} \sin\left(\frac{n\pi x}{L}\right) \bigg|_{0}^{L} \]

\[ = \frac{1}{L} \sin(n\pi) - \frac{1}{L} \frac{1}{n\pi} \]

\[ = \sin(n\pi) - 0 = 0. \]

We next find \( b_n, n = 1, 2, \ldots \),

\[ b_n = \frac{1}{L} \int_{-L}^{L} f(x) \sin\left(\frac{n\pi x}{L}\right) \, dx = \frac{1}{L} \int_{0}^{L} 1 \sin\left(\frac{n\pi x}{L}\right) \, dx \]

\[ = \frac{1}{L} \left[ -\cos\left(\frac{n\pi x}{L}\right) \right]_{0}^{L} \]

\[ = -\cos(n\pi) + 1 = -\frac{(-1)^n}{n\pi} + \frac{1}{n\pi} = 0. \]

Hence

\[ \mathcal{F}(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} \left[ a_n \cos\left(\frac{n\pi x}{L}\right) + b_n \sin\left(\frac{n\pi x}{L}\right) \right] \]

\[ = \frac{1}{2} + \sum_{n=1}^{\infty} \frac{1 - (-1)^n}{\pi n} \sin\left(\frac{n\pi x}{L}\right) \]

(b) (2 points) At which points on \([-L, L]\), do \( \mathcal{F}(x) \) and \( f(x) \) NOT agree?

Solution: Except at the end points and the discontinuity point, \( \mathcal{F}(x) = f(x) \). Hence we only need to check points \( x = -L, 0, L \). At 0, \( f(0) = 1 \) but \( \mathcal{F}(1) = 1/2 \). Similarly, at \( x = -L, f(x) = 0 \) whereas \( \mathcal{F}(-L) = 1/2 \). Finally, at \( x = L \) we have \( f(L) = 1 \) and \( \mathcal{F}(L) = 1/2 \). They do not agree at \( x = -L, 0, L \) and at all other points they agree.

(c) (3 points) Verify that

\[ \frac{\pi}{4} = \sum_{k=0}^{\infty} \frac{(-1)^k}{2k+1}. \]

Solution: Notice that \( 1 - (-1)^n = 0 \) when \( n \) is even and it is 2 when \( n \) is odd. Hence if we
replace \( n = 2k + 1 \) we have

\[
\mathcal{F}(x) = \frac{1}{2} + \sum_{k=0}^{\infty} \frac{2}{\pi(2k+1)} \sin\left(\frac{(2k+1)\pi x}{L}\right).
\]

From part (b) we know that \( \mathcal{F}(x) = f(x) \) at \( x = L/2 \). From this we get

\[
1 = f\left(\frac{\pi}{2}\right) = \mathcal{F}\left(\frac{\pi}{2}\right) = \frac{1}{2} + \sum_{k=0}^{\infty} \frac{2}{\pi(2k+1)} \sin\left((2k+1)\frac{\pi}{2}\right).
\]

After some algebra we get

\[
\frac{\pi}{4} = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{2k - 1} = \sum_{k=0}^{\infty} \frac{(-1)^k}{2k + 1}.
\]
2. (10 points) Solve

\[
\begin{cases}
 u_t - u_{xx} = e^{-4t} \cos(t) \sin(2x), & 0 \leq x \leq \pi, \ t \geq 0, \\
 u(0, t) = 0, \ u(\pi, t) = 0, \\
 u(x, 0) = \sin(3x).
\end{cases}
\] (1)

Solution: Since the boundary conditions are homogeneous, we can pass to the second step. That is we shall look for where

\[
\begin{cases}
 (u_1)_t - (u_1)_{xx} = 0, & 0 \leq x \leq \pi, \ t \geq 0, \\
 u_1(0, t) = 0, \ u_1(\pi, t) = 0, \\
 u_1(x, 0) = \sin(3x).
\end{cases}
\] (2)

and \( u_2 \) solves the non-homogeneous heat equation with zero initial condition

\[
\begin{cases}
 (u_2)_t - (u_2)_{xx} = e^{-4t} \cos(t) \sin(2x), & 0 \leq x \leq \pi, \ t \geq 0, \\
 u_2(0, t) = 0, \ u_2(\pi, t) = 0, \\
 u_2(x, 0) = 0.
\end{cases}
\] (3)

Then by linearity of the heat equation we conclude that \( u(x, t) = u_1(x, t) + u_2(x, t) \) solves our original equation (1). We shall first focus on \( u_1 \), we know the general solution is (you can use the proposition from the book, or our lecture notes)

\[ u_1(x, t) = \sum_{n_1}^{\infty} C_n e^{-n^2 t} \sin(nx) \]

and using the initial condition for \( u_1 \) we get

\[ u_1(x, 0) = \sin(3x) = \sum_{n_1}^{\infty} C_n \sin(nx) \]

which tells us \( C_3 = 1 \) and all other \( C_n = 0. \) Hence

\[ u_1(x, t) = e^{-9t} \sin(3x). \]

solves (2). Now we focus on \( u_2 \). To solve (6), we shall use the Duhamel’s principle. That is,

\[ u_2(x, t) = \int_0^t \tilde{v}(x, t-s; s) \, ds \]

where \( \tilde{v} \) solves

\[
\begin{cases}
 \tilde{v}_t - \tilde{v}_{xx} = 0, & 0 \leq x \leq \pi, \ t \geq 0, \\
 \tilde{v}(0, t; s) = 0, \ \tilde{v}(\pi, t; s) = 0, \\
 \tilde{v}(x, 0; s) = e^{-4s} \cos(s) \sin(2x).
\end{cases}
\] (4)

Here you should think of \( e^{-4s} \cos(s) \) as a constant independent of \( t \). We know that the general solution is

\[ \tilde{v}(x, t; s) = \sum_{n_1}^{\infty} C_n e^{-n^2 t} \sin(nx) \]
and using the initial condition in (9) we get

\[ \vartheta(x, 0; s) = \sum_{n=1}^{\infty} C_n \sin(nx) = e^{-4s} \cos(s) \sin(2x) \]

which tells us that \( C_2 = e^{-4s} \cos(s) \) and all other \( C_n = 0 \). Hence we have (for \( n = 2 \))

\[ \vartheta(x, t; s) = e^{-4s} \cos(s)e^{-4t} \sin(2x). \]

Using Duhamel’s principle we have

\[ u_2(x, t) = \int_0^t \vartheta(x, t - s; s) ds = \int_0^t e^{-4s} \cos(s) e^{-4(t-s)} \sin(2x) ds \]

To find \( u_2 \) we need to find that integral. After some algebra we see that

\[ u_2(x, t) = \int_0^t e^{-4s} \cos(s) e^{-4(t-s)} \sin(2x) ds = e^{-4t} \sin(2x) \int_0^t \cos(s) ds = e^{-4t} \sin(2x) \sin(t) \]

Combining this with \( u_1 \) we get

\[ u(x, t) = u_1(x, t) + u_2(x, t) = e^{-9t} \sin(3x) + e^{-4t} \sin(2x) \sin(t) \]

is the solution of (1).
3. (10 points) Consider the Heat equation

\[
\begin{cases}
    u_t - 2u_{xx} = 0, & 0 \leq x \leq 1, \ t \geq 0, \\
    u(0, t) = -1, \ u_x(1, t) = 1, \\
    u(x, 0) = x + \sin\left(\frac{3\pi x}{2}\right) - 1.
\end{cases}
\]

where the boundary conditions are non-homogeneous. Transform the equation into a new one with homogeneous boundary conditions. (You do not need to solve the new equation).

Solution: We first should make the non-homogeneous boundary conditions homogeneous. To this end, we look for time-independent or steady-state solution \( u_p(x, t) \) to heat equation.

We know that the only steady state solution is \( u_p(x, t) = ax + b \) for some \( a, b \). We will figure out \( a, b \) so that \( u_p(0, t) = -1 \) and \( u_x(1, t) = 1 \) (which are our non-homogeneous boundary conditions). Hence \( u_p(0, t) = b = -1 \) and \( (u_p(x, t))_x = a \) which we want to be 1 when \( x = 1 \), i.e. \( (u_p(x, t))_x = a = 1 \). Hence we get \( u_p(x, t) = x - 1 \). We now let

\[
v(x, t) = u(x, t) - u_p(x, t)
\]

and hope that \( v \) will satisfy the heat equation with homogeneous boundary conditions. To see this, as \( u \) solves (5), and \( u_p \) is steady-state solution to heat equation, and heat equation is linear \( v \) solves the heat equation \( v_t = 2v_{xx} \). Next, we check the boundary conditions

\[
v(0, t) = u(0, t) - u_p(0, t) = -1 - (-1) = 0 \quad \text{and} \quad v_x(1, t) = u_x(1, t) - (u_p(1, t))_x = 1 - 1 = 0.
\]

Hence \( v \) satisfies the homogeneous boundary conditions. We next see the initial condition

\[
v(x, 0) = u(x, 0) - u_p(x, 0) = x + \sin\left(\frac{3\pi x}{2}\right) - 1 - (x - 1) = \sin\left(\frac{3\pi x}{2}\right).
\]

If we summarize what we got for \( v \) is that

\[
\begin{cases}
    v_t = 2v_{xx} & 0 \leq x \leq 1, \ t \geq 0 \\
    v(0, t) = 0 & v_x(1, t) = 0 \\
    v(x, 0) = \sin\left(\frac{3\pi x}{2}\right).
\end{cases}
\]
4. (10 points) Describe the steps how to solve the following heat equation

$$\begin{cases}
  u_t - ku_{xx} = h(x,t), & 0 \leq x \leq L, \ t \geq 0, \\
  u(0,t) = a(t), \ u(L,t) = b(t), \\
  u(x,0) = f(x).
\end{cases} \quad (6)$$

Solution:

Step 1: The boundary conditions are non-homogeneous, we will make them homogeneous. To do this, we let

$$u_p(x,t) := \frac{1}{L} (b(t) - a(t)) x + a(t)$$

Now consider

$$v(x,t) = u(x,t) - u_p(x,t).$$

We should see that

$$v(0,t) = u(0,t) - u_p(0,t) = a(t) - a(t) = 0 \quad \text{and} \quad v(L,t) = u(L,t) - u_p(L,t) = b(t) - b(t) = 0.$$

On the other hand,

$$v_t - kv_{xx} = u_t - ku_{xx} - (u_p)_t + k(u_p)_{xx} = h(x,t) - \frac{1}{L} (b'(t) - a'(t)) x - a'(t) =: H(x,t)$$

and

$$v(x,0) = u(x,0) - u_p(x,0) = f(x) - \frac{1}{L} (b(0) - a(0)) x + a(0) = F(x).$$

Hence $v$ satisfies the following equation

$$\begin{cases}
  v_t - kv_{xx} = H(x,t) & 0 \leq x \leq L, \ t \geq 0 \\
  v(0,t) = 0 \\
  v(L,t) = 0 \\
  v(x,0) = F(x).
\end{cases}$$

Step 2: From this we consider $v(x,t) = v_1(x,t) + v_2(x,t)$ where where $u_1$ solves the homogeneous heat equation;

$$\begin{cases}
  (u_1)_t - (u_1)_{xx} = 0, & 0 \leq x \leq L, \ t \geq 0, \\
  u_1(0,t) = 0, \ u_1(L,t) = 0, \\
  u_1(x,0) = F(x).
\end{cases} \quad (7)$$

and $u_2$ solves the non-homogeneous heat equation with zero initial condition

$$\begin{cases}
  (u_2)_t - (u_2)_{xx} = H(x,t), & 0 \leq x \leq L, \ t \geq 0, \\
  u_2(0,t) = 0, \ u_2(L,t) = 0, \\
  u_2(x,0) = 0.
\end{cases} \quad (8)$$

Step 3: Find $v_1$. In case $F(x)$ is not given in terms of sine function we then need to do the half range extension and then find the Fourier series of $F(x)$ and finally find $v_1.$
Step 4: Using Duhamel’s principle find \( v_2 \). That is,

\[
u_2(x, t) = \int_0^t \tilde{v}(x, t-s; s) \, ds
\]

where \( \tilde{v} \) solves

\[
\begin{cases}
\tilde{v}_t - \tilde{v}_{xx} = 0, & 0 \leq x \leq L, \ t \geq 0, \\
\tilde{v}(0, t; s) = 0, & \tilde{v}(L, t; s) = 0, \\
\tilde{v}(x, 0; s) = H(x, s; s).
\end{cases}
\] (9)

Step 5: Find \( \tilde{v} \) first and in case \( H(x, s; s) \) is not given in terms of sine function we then need to do the half range extension and then find the Fourier series of \( H(x, s; s) \) and finally find \( \tilde{v} \). Then find \( v_2 \).

Step 6: Combining all of these we get

\[
u(x, t) = v(x, t) + u_p(x, t) = v_1(x, t) + v_2(x, t) + u_p(x, t).
\]
5. (5 points (bonus)) Let $u$ be a solution to the following heat equation

$$
\begin{align*}
\begin{cases}
  u_t &= u_{xx}, & 0 \leq x \leq \pi, \ t \geq 0, \\
  u_x(0,t) &= 0, \ u_x(\pi,t) = 0, & t \geq 0 \\
  u(x,0) &= f(x), & 0 < x < \pi.
\end{cases}
\end{align*}
$$

Show that

$$
I(t) = \int_{0}^{\pi} e^{u(x,t)} \, dx
$$

decreases as a function of $t$ for $t \geq 0$.

**Solution:** To show $I(t)$ decreases, we show that $I'(t) \leq 0$ for every $t \geq 0$. To this end,

$$
I'(t) = \frac{d}{dt} \left\{ \int_{0}^{\pi} e^{u(x,t)} \, dx \right\} = \int_{0}^{\pi} \frac{d}{dt} e^{u(x,t)} \, dx = \int_{0}^{\pi} u_t(x,t) e^{u(x,t)} \, dx.
$$

Since $u_t = u_{xx}$ for all $t \geq 0$ and $0 \leq x \leq \pi$ we have

$$
I'(t) = \int_{0}^{\pi} u_t(x,t) e^{u(x,t)} \, dx = \int_{0}^{\pi} u_{xx}(x,t) e^{u(x,t)} \, dx.
$$

Now we do integrate by parts and use the boundary conditions to get

$$
I'(t) = \left[ u_x(x,t) e^{u(x,t)} \right]_{0}^{\pi} - \int_{0}^{\pi} u_x(x,t) \frac{d}{dt} e^{u(x,t)} \, dx = u_x(\pi,t) e^{u(\pi,t)} - u_x(0,t) e^{u(0,t)} - \int_{0}^{\pi} u_x^2(x,t) e^{u(x,t)} \, dx
$$

Since $u_x^2(x,t)$ and $e^{u(x,t)}$ are always non-negative, therefore the right-hand side is always non-positive. That is $I'(t) \leq 0$ for every $t$. Hence $I(t)$ decreases as a function of $t$ for $t \geq 0$.
